#### Abstract

A field experiment was conducted during 2022-23 and 2023-24 to assess the effect of varieties, nutrient levels, and weed management practices on yield attributes and yield of finger millet (*Eleusine coracana*) under rainfed conditions of the Bastar plateau. The results revealed significant variation among treatments. Among varieties, CG Ragi-2 (V<sub>2</sub>) recorded the highest number of fingers hill<sup>-1</sup> (9.78), seeds finger<sup>-1</sup> (230.1), ear head length (10.24 cm), seed yield (23.84 q ha<sup>-1</sup>), straw yield (42.37 q ha<sup>-1</sup>), and harvest index (36.01%), outperforming Indira Ragi-1 (V<sub>1</sub>) and CG Ragi-3 (V<sub>3</sub>). Nutrient levels significantly influenced crop performance, with 125% RDN (N<sub>3</sub>) yielding the highest values for number of fingers hill<sup>-1</sup> (9.64), seeds finger<sup>-1</sup> (226.8), seed yield (23.47 q ha<sup>-1</sup>), and straw yield (41.82 q ha<sup>-1</sup>), indicating the importance of adequate nitrogen for enhancing physiological and reproductive processes. Among weed management practices, hand weeding twice (W<sub>3</sub>) resulted in superior yield attributes and yield, with seed yield (23.51 q ha<sup>-1</sup>), straw yield (42.01 q ha<sup>-1</sup>), and harvest index (35.88%) on mean basis. The interaction of CG Ragi-2 × 125% RDN × hand weeding twice recorded the highest seed yield (25.36 q ha<sup>-1</sup>), highlighting the synergistic effect of genotype, fertility, and weed control. This integrated approach proved most effective for maximizing finger millet productivity under rainfed conditions.

Keywords: Nutrient levels, weed management, cultivars, seed yield, straw yield and harvest index

# Introduction

Finger millet (*Eleusine coracana* L.), commonly known as ragi, is a vital staple and nutritional cereal crop cultivated primarily in arid and semi-arid regions of India. It holds a significant position in ensuring food and nutritional security, particularly for tribal and marginal farming communities, due to its adaptability to adverse climatic conditions, low input requirements, and exceptional nutritional composition rich in calcium, dietary fibre, and essential amino acids.

Despite its importance, finger millet productivity in many regions, including Chhattisgarh, remains suboptimal. This is primarily due to imbalanced nutrient management and unchecked weed infestation, which lead to nutrient competition, reduced photosynthetic efficiency, and poor crop stand (Rana *et al.*, 2020) [13]. The Bastar plateau region of Chhattisgarh, characterized by its rainfed conditions, acidic soils, and traditional cultivation practices, presents unique challenges and opportunities for enhancing finger millet productivity through improved agronomic interventions.

Nutrient management, particularly nitrogen, phosphorus, and potassium (NPK), plays a critical role in influencing the physiological and reproductive growth of finger millet. Adequate nutrient supply enhances panicle formation, grain filling, and ultimately yield. However, excess or unbalanced fertilization can also lead to poor nutrient use efficiency and environmental degradation. Therefore, site-specific nutrient management is essential to achieve both productivity and sustainability goals Weed competition is another major constraint in finger millet production, especially during the early growth stages when the crop is less competitive. Weed infestation not only reduces

yield but also deteriorates grain quality. Integrated weed management practices, combining cultural and chemical methods, have been shown to be effective in minimizing yield losses and improving nutrient uptake and resource use efficiency (Patel *et al.*, 2018) <sup>[12]</sup>. In this context, the present investigation was undertaken to assess the influence of varying nutrient levels and weed management practices on the yield attributes and yield of different finger millet cultivars under the agro-ecological conditions of the Bastar plateau. The study aims to identify optimum combinations of cultivar, nutrient regime, and weed control strategy for enhancing finger millet productivity in the region.

#### **Materials and Methods**

The present field investigation titled "Impact of nutrient levels and weed management on yield attributes and productivity of finger millet (Eleusine coracana L.) cultivars in the Bastar Plateau of Chhattisgarh" was conducted during the summer seasons of 2021 and 2022 at the Instructional-cum-Research Farm, S.G. College of Agriculture and Research Station, Jagdalpur, under Indira Gandhi Krishi Vishwavidyalaya (IGKV), Chhattisgarh. The experimental site is located between 19°5′ to 20°15' N latitude and 80°30' to 82°15' E longitude, with an elevation of 552 meters above mean sea level. The region experiences a sub- humid climate with monsoonal rainfall, receiving an annual precipitation of 1200-1400 mm, mostly concentrated between June and September.

The experiment was laid out in a split-split plot design with three replications. Treatments consisted of three cultivars: Indira Ragi-1 (V1), CG Ragi-2 (V2), and CG Ragi-3 (V3) as main plots; three nutrient levels 75% RDN (N1), 100% RDN (N<sub>2</sub>), and 125% RDN (N<sub>3</sub>) as sub-plots; and four weed management practices as sub-sub plots: W1 (pre-emergence application of Oxadiargyl @ 80 g a.i. ha<sup>-1</sup> + one mechanical weeding at 40 DAS), W2 (post- emergence application of Bispyribac-sodium @ 20 g a.i. ha<sup>-1</sup>), W3 (hand weeding twice at 20 and 40 DAS), and W4 (weedy check). The recommended dose of nutrients was 60:30:30 kg N: P<sub>2</sub>O<sub>5</sub>:K<sub>2</sub>O ha<sup>-1</sup>, applied through urea, single super phosphate, and muriate of potash, respectively. Nitrogen was applied in two equal splits—half as basal and half at 30 DAS. The crop was sown manually in rows at 30 cm  $\times$  10 cm spacing, using a seed rate of 5 kg ha<sup>-1</sup>. The field was prepared using a tractor-drawn cultivator and levelled with plankers. Gap filling was performed at 10 DAS. Due to adequate rainfall, irrigation was not necessary during the cropping period. Uniform agronomic practices were maintained across all treatments.

# Results and Discussion Number of fingers hill-1

The data on the number of fingers hill-1 in finger millet, as influenced by varieties, nutrient levels, and weed management practices, are presented in Table 1, showing significant differences across treatments during both years and on a mean basis. Among the varieties, Indira Ragi-1 (V<sub>1</sub>) recorded the highest number of fingers hill<sup>-1</sup> in the first year, while CG Ragi- 2 (V<sub>2</sub>) produced significantly more fingers hill<sup>-1</sup> in the second year and on average, likely due to genotypic variation in panicle development and plant vigour (Singh *et al.*, 2018; Sharma & Patel, 2020). Nutrient

application also had a marked effect, with 125% RDN (N<sub>3</sub>) consistently resulting in the highest number of fingers hill<sup>-1</sup> across both years, reflecting the importance of adequate nutrient availability in supporting photosynthate accumulation, tiller retention, and reproductive development (Kumar *et al.*, 2017) <sup>[7]</sup>. Weed management played a crucial role as well, with hand weeding twice (W3) yielding the highest number of fingers hill<sup>-1</sup> in both years and on a mean basis, likely due to reduced competition for essential resources, which favoured panicle initiation and growth (Verma *et al.*, 2016) <sup>[27]</sup>.

# Number of seeds finger -1

The number of seeds finger-1 in finger millet, as influenced by nutrient levels and weed management practices, is presented in Table 1, with statistically significant differences observed across treatments during both years and on a mean basis. Among the varieties, CG Ragi-2 (V2) consistently produced the highest number of seeds finger<sup>-1</sup> compared to Indira Ragi-1 (V1) and CG Ragi-3 (V3) in both years and on average, indicating superior reproductive efficiency and panicle fertility attributed to genotypic potential (Sharma et al., 2020; Meena et al., 2021) [20, 9]. Nutrient application had a significant effect, with 125% RDN (N<sub>3</sub>) recording the maximum number of seeds finger<sup>-1</sup>, followed by 100% RDN (N2), while the lowest was observed under 75% RDN (N1), highlighting the role of higher nutrient availability in enhancing photosynthate production and its allocation to reproductive structures, thereby improving seed filling (Kumar et al., 2018; Singh and Verma, 2020) [21, 5]. Weed management practices also significantly affected seed number finger-1, with hand weeding twice (W3) resulting in the highest values, followed by pre-emergence herbicide with mechanical weeding (W1), and post-emergence herbicide (W2), while the weedy check (W<sub>4</sub>) recorded the lowest. These results underscore the importance of effective weed control in minimizing competition for nutrients and moisture during key reproductive phases, corroborating findings by Patel et al. (2017) [11] and Yadav et al. (2022) [28].

# Test weight of seed (g)

The data on the test weight of finger millet seeds as influenced by nutrient levels, weed management practices, and varieties are presented in Table 2. Although the differences were statistically non-significant, clear varietal trends were observed. CG Ragi-2 (V<sub>2</sub>) consistently recorded the highest test weight across both years and on a pooled mean basis, followed by Indira Ragi-1 (V1), while the lowest values were noted in CG Ragi-3 (V<sub>3</sub>). This trend suggests that genotypic variation influences assimilate partitioning and grain filling efficiency, which ultimately determines seed weight (Rana et al., 2020; Kumari et al., 2021) [8, 13]. Similarly, nutrient levels did not show statistically significant differences; however, a consistent trend of increased test weight with higher nutrient application was evident, with 125% RDN (N<sub>3</sub>) showing the highest values, followed by 100% RDN (N2), and the lowest under 75% RDN (N<sub>1</sub>). These results imply that higher nutrient availability may enhance photosynthetic efficiency and assimilate translocation to developing grains (Singh and Yadav, 2019; Patel et al., 2017) [6, 11]. Weed management

practices also exhibited non-significant effects on test weight, but the trend indicated that hand weeding twice  $(W_3)$  resulted in the highest test weight, followed by preemergence herbicide with mechanical weeding  $(W_1)$ , and post-emergence herbicide  $(W_2)$ , while the weedy check  $(W_4)$  recorded the lowest. This pattern supports the premise that effective weed control improves resource availability, thereby enhancing grain filling and seed development  $(Yadav\ et\ al.,\ 2022)^{[28]}$ .

### Ear head length of finger (cm)

The data on ear head length of fingers in finger millet as influenced by different varieties, nutrient levels, and weed management practices are presented in Table 1, with statistical analysis revealing significant differences among treatments during both years and on a mean basis. Among the varieties, CG Ragi-2 (V2) consistently recorded significantly higher ear head length compared to Indira Ragi-1 (V1) and CG Ragi-3 (V3) in both years and on average, likely due to its superior genetic potential for spike elongation and sink strength, which influence reproductive traits (Sharma et al., 2018; Rao et al., 2021) [15, 19]. Nutrient levels had a marked effect, with 125% RDN (N<sub>3</sub>) resulting in the longest ear heads, followed by 100% RDN (N2), while the shortest ear heads were observed under 75% RDN (N1). This can be attributed to increased nutrient availability enhancing meristematic activity, cell elongation, and spike growth via improved photosynthetic efficiency and assimilate translocation (Kumar et al., 2019; Verma et al., 2020) [5, 6]. Weed management also significantly influenced ear head length, with hand weeding twice (W<sub>3</sub>) producing the longest ear heads in both years and on mean basis. However, it was statistically at par with pre-emergence application of Oxadiargyl (80 g a.i. ha<sup>-1</sup>) + one mechanical weeding at 40 DAT (W<sub>1</sub>) on the pooled mean. Effective weed control likely reduced competition for essential resources, facilitating better reproductive growth and panicle development (Mishra and Das, 2017; Bhandari et *al.*, 2022) [1, 10].

#### Seed yield (kg ha-1)

Seed yield of finger millet was significantly influenced by variety, nutrient levels, and weed management practices across both years and on a mean basis, as shown in Table 2, highlighting the combined effect of genetic, nutritional, and agronomic factors on crop productivity. Among the cultivars, CG Ragi-2 (V2) recorded the highest seed yield, followed by Indira Ragi-1 (V<sub>1</sub>), while CG Ragi-3 (V<sub>3</sub>) consistently produced the lowest yield. These differences can be attributed to genotypic variation in tillering ability, spikelet fertility, grain filling efficiency, and biomass partitioning (Sharma et al., 2018; Rao et al., 2021; Meena et al., 2021) [19, 15, 9]. Superior-performing varieties are also known for their higher physiological efficiency and adaptability to environmental conditions (Rana et al., 2020) [13]. Seed yield increased progressively with higher nutrient application, with 125% RDN (N<sub>3</sub>) producing significantly greater yields than 100% RDN (N2) and 75% RDN (N1), suggesting that enhanced nutrient supply improves chlorophyll content, photosynthetic activity, and assimilate translocation toward grain development (Kumar et al., 2019; Singh and Yadav, 2019; Verma et al., 2020) [5, 22, 5]. Weed management also had a significant impact, with hand weeding twice (W<sub>3</sub>) resulting in the highest seed yield, followed by pre-emergence herbicide combined with mechanical weeding (W<sub>1</sub>), and post-emergence herbicide (W<sub>2</sub>), while the lowest yield was observed in the weedy check (W<sub>4</sub>). Effective weed control likely minimized competition for water, nutrients, and light, thereby supporting enhanced reproductive growth and grain filling (Mishra and Das, 2017; Bhandari *et al.*, 2022; Yadav *et al.*, 2022) [1, 10].

The interaction effects of variety  $\times$  nutrient levels, variety  $\times$ weed management, nutrient levels × weed management, and the three-way interaction of variety  $\times$  nutrient levels  $\times$  weed management on seed yield (kg ha-1) of finger millet were found to be statistically significant across both years and on a mean basis (Table 3-6). Among the variety × nutrient level interactions, the combination of CG Ragi-2 (V<sub>2</sub>) with 125% RDN (N<sub>3</sub>) recorded the highest seed yield, significantly surpassing all other combinations. This superior performance is attributed to the higher genetic yield potential of CG Ragi-2 and its responsiveness to increased nitrogen input, corroborating the findings of Sharma et al. (2016) and Kumari et al. (2017). In the variety × weed management interaction, CG Ragi-2 (V2) under hand weeding twice (W<sub>3</sub>) produced the highest seed yield across all observations, likely due to efficient weed suppression that reduced resource competition and enhanced plant growth and productivity (Chauhan and Johnson, 2010; Tiwari et al., 2018)  $^{[2, 25]}$ . Similarly, in the nutrient level  $\times$ weed management interaction, 125% RDN (N<sub>3</sub>) combined with hand weeding twice (W3) yielded significantly more than other treatment combinations, reflecting the synergistic benefits of higher nutrient availability and effective weed control (Rao et al., 2009; Gharde et al., 2018) [14, 3]. The three-way interaction among CG Ragi-2 (V2), 125% RDN (N<sub>3</sub>), and hand weeding twice (W<sub>3</sub>) consistently resulted in the highest seed yield across both years and on average, underscoring the importance of integrating high-yielding cultivars, optimal nutrient management, and efficient weed control for maximizing finger millet productivity under rainfed conditions (Somasundaram et al., 2009) [24].

#### Straw yield (kg ha-1)

Straw yield of finger millet was significantly influenced by variety, nutrient levels, and weed management across both years and on a mean basis (Table 2), emphasizing the importance of integrated agronomic practices in enhancing total biomass productivity. Among the varieties, CG Ragi-2 (V2) consistently recorded the highest straw yield, followed by Indira Ragi-1 (V<sub>1</sub>), while the lowest was observed in CG Ragi-3 (V<sub>3</sub>). The superior performance of V<sub>2</sub> is likely due to its vigorous vegetative growth, higher leaf area index, and robust plant architecture, all of which contribute to greater dry matter accumulation (Sharma et al., 2018; Rao et al., 2021) [15, 19]. Genotypic variation in physiological efficiency and biomass partitioning is a known factor influencing straw yield in small millets (Meena et al., 2021) [9]. Nutrient levels also had a significant effect, with 125% RDN (N<sub>3</sub>) resulting in the highest straw yield, followed by 100% RDN (N2) and the lowest under 75% RDN (N1). This trend can be attributed to improved chlorophyll content, photosynthesis, and vegetative growth under higher nutrient availability,

particularly nitrogen, which plays a key role in cell division and elongation essential for shoot and leaf development (Kumar *et al.*, 2019; Verma *et al.*, 2020; Singh and Yadav, 2019) <sup>[5, 6, 22]</sup>. Weed management significantly impacted straw yield, with hand weeding twice (W<sub>3</sub>) yielding the highest, followed by pre-emergence herbicide + mechanical weeding (W<sub>1</sub>) and post-emergence herbicide (W<sub>2</sub>), while the weedy check (W<sub>4</sub>) recorded the lowest. Effective weed control during early crop growth likely reduced competition for vital resources, allowing for better canopy development and overall biomass production (Mishra and Das, 2017; Bhandari *et al.*, 2022) <sup>[1, 10]</sup>.

The interaction effects of variety  $\times$  nutrient levels, variety  $\times$ weed management, nutrient levels × weed management, and the three-way interaction of variety × nutrient levels × weed management on straw yield (kg ha<sup>-1</sup>) of finger millet were statistically significant during both years and on a mean basis (Table 7-10). Among the variety × nutrient level combinations, CG Ragi-2 (V2) with 125% RDN (N3) consistently produced the highest straw yield, significantly outperforming other treatments. This enhanced biomass accumulation is attributed to the vigorous vegetative growth and higher structural biomass potential of CG Ragi-2, further amplified by increased nitrogen availability that promotes cell division and elongation (Sharma et al., 2016; Kumari et al., 2017) [20, 7]. In the variety  $\times$  weed management interaction, CG Ragi-2 (V2) with hand weeding twice (W<sub>3</sub>) recorded significantly higher straw yield due to improved weed suppression, which minimized competition for light, nutrients, and water facilitating robust plant growth (Chauhan and Johnson, 2010; Tiwari *et al.*, 2018) <sup>[2, 25]</sup>. Likewise, in the nutrient level × weed management interaction, 125% RDN (N<sub>3</sub>) combined with hand weeding twice (W<sub>3</sub>) yielded the highest biomass, reflecting the synergistic effect of optimal nutrition and effective weed control in enhancing vegetative vigour (Rao *et al.*, 2009; Gharde *et al.*, 2018) <sup>[14, 3]</sup>. The three-way interaction of CG Ragi-2 (V<sub>2</sub>), 125% RDN (N<sub>3</sub>), and hand weeding twice (W<sub>3</sub>) recorded the highest straw yield across both years and on a mean basis, indicating that integrating a high-performing genotype with adequate nutrient supply and efficient weed management is essential for maximizing straw yield in finger millet under rainfed conditions (Somasundaram *et al.*, 2009) <sup>[24]</sup>.

#### Harvest index (%)

The harvest index (HI) of finger millet was significantly influenced by variety, nutrient levels, and weed management across both years and on a mean basis (Table 2), underscoring the importance of integrated agronomic practices in optimizing biomass partitioning towards grain production. Among the varieties, CG Ragi-2 (V<sub>2</sub>) consistently recorded the highest HI, followed by Indira Ragi-1 (V<sub>1</sub>), while CG Ragi-3 (V<sub>3</sub>) recorded the lowest across both years and on mean basis, likely due to genotypic traits such as superior assimilate translocation and grain filling efficiency (Sharma *et al.*, 2018; Rao *et al.*, 2021) [15, 19]. Nutrient levels also had a

significant effect, with the highest HI observed under 100% RDN (N<sub>2</sub>), statistically at par with 125% RDN (N<sub>3</sub>), and the lowest under 75% RDN (N<sub>1</sub>), indicating that optimal nutrient supply enhances photosynthesis and dry matter allocation to the grain (Kumar *et al.*, 2019; Reddy *et al.*, 2020) [15, 19]. Weed management practices significantly influenced HI, with hand weeding twice (W<sub>3</sub>) resulting in the highest index, followed by pre-emergence herbicide + mechanical weeding (W<sub>1</sub>) and post-emergence herbicide (W<sub>2</sub>), while the lowest HI was recorded under the weedy check (W<sub>4</sub>). Effective weed control likely reduced competition for nutrients and light, thereby promoting reproductive growth (Mishra & Das, 2017) [1].

The interaction between variety and nutrient level (Table 11) was also significant, with the combination of CG Ragi-2 ( $V_2$ ) and 100% RDN ( $N_2$ ) recording the highest HI, statistically at par with  $V_2 \times 125\%$  RDN ( $N_3$ ). The improved HI under these combinations may be attributed to efficient dry matter partitioning towards grain yield, driven by genotypic vigour and balanced nutrient availability (Sharma *et al.*, 2016; Kumari *et al.*, 2017; Ramesh *et al.*, 2002) [20, 7, 16]. These findings highlight the need to select nutrient-responsive genotypes and optimize nitrogen levels to enhance physiological efficiency and grain productivity in finger millet.

# Conclusion

The study clearly demonstrated that the productivity and yield attributes of finger millet are significantly influenced by the interaction of varieties, nutrient levels, and weed management practices. Among the varieties, CG Ragi-2 (V<sub>2</sub>) consistently outperformed others in terms of number of fingers hill<sup>-1</sup>, seeds finger<sup>-1</sup>, ear head length, seed yield, straw yield, and harvest index, highlighting its superior genetic potential and adaptability under rainfed conditions. Nutrient application at 125% recommended dose of nitrogen (RDN) (N<sub>3</sub>) was found to be most effective in enhancing all yield attributes and yields, emphasizing the critical role of optimal nutrient availability, particularly nitrogen, in improving physiological processes like photosynthesis,

tillering, and assimilate translocation. Among the weed management practices, hand weeding twice (W<sub>3</sub>) proved to be the most effective, consistently recording the highest values for all parameters. This indicates the importance of efficient weed control in reducing competition for essential growth resources and enhancing crop performance. Significant interaction effects were observed across variety × nutrient level, variety × weed management, nutrient level × weed management, and the three-way interaction. The combination of CG Ragi-2 (V2), 125% RDN (N3), and hand weeding twice (W3) consistently recorded the highest seed and straw yields, demonstrating the synergistic impact of integrating high-yielding cultivars, adequate nutrient supply, and effective weed control practices. Overall, the findings underscore the importance of adopting an integrated crop management approach, which includes genotype selection, site-specific nutrient application, and timely weed control, for maximizing yield and resource-use efficiency in finger millet under rainfed agro-ecosystems.
